

HIGH-LEVEL SYSTEM SOFTWARE ARCHITECTURE

OVERVIEW

A.R.G.U.S. is designed as an **event-driven, real-time** safety device that continuously monitors a **visual reference** during robotic operation. Each **camera frame** is treated as a **discrete event** and processed through a bounded vision safety check. The result is evaluated by a **guardian state machine**, which enforces safety constraints and can transition the system into a frozen safe mode when unsafe conditions are detected. Motion control commands are gated through a robot interlock layer(may need to discuss how this aspect works entirely?)
